KARDIOLÓGIAI  
KÖZPONT

Cardiac Center, Radiology Unit

**Clinical Cardiovascular  
Physiology**

# Magnetic resonance

- History
  - Steady-state free precession in nuclear magnetic resonance
    - **Phys Rev 112(5):1693-1701 (1958)**, HY Carr
  - Gadolinium-DTPA as a contrast agent in MRI: initial clinical experience in 20 patients
    - **Am J Roentgenol 143(2):215-227 (1984)**
  - Magnetic resonance imaging of the heart: a review of experience in 172 subjects
    - **Radiology 155(3):671-679 (1985)**, CB Higgins

# Magnetic resonance

- No ionizing radiation
- Superb CNR
- Accurate
- Flow quantification
- Time consuming
- Monitoring
- Requires cooperation
- Complicated

# Long axis

# Constant volume theorem

- The volume of the pericardial sac remains nearly constant over the cardiac cycle
  - It deviates less than 5% from the equilibrium
  - Prof Kovács J Sándor
    - **AJP Heart Circ Physiol 285(5):H2027 (2003)**

# HCM in an athlete

# DE kvantifikáció: 63g scar out of 360g

The screenshot displays the QMass MR 7.2 software interface. The main window shows a cardiac MRI scan with a red contour for the myocardium and a green contour for the scar tissue. The software has calculated the following results:

Parameter	Value
Total myocardial mass	360,33 g
Scar tissue mass	63,20 g
Scar tissue volume	60,19 ml
Scar tissue percentage	18 %
Nonviable mass	5,33 g
Nonviable volume	5,08 ml
Nonviable percentage	1 %
Transmurality threshold	50 %

Technical parameters for the scan are also displayed:

- TR: 5,49ms
- TE: 2,52ms
- Ti: 0,00ms
- TD: 773ms
- SL: 12
- PH: 1
- SP: 88,00mm
- SI th: 8mm

Additional information shown includes: Total mass: 360,33g, Scar tissue: 63,20g / 18%, WW: 138, WL: 2 090, Zoom: 175%.

The interface also shows a grid of 18 small images representing different slices of the heart, with the current slice highlighted in red. The software version is 7.2, and the user is logged in as 'mr - atoth@atoth.sote.h...'. The system tray shows the date and time as 21:21.

# Breathing maneuvers + O<sub>2</sub>-sensitive MR

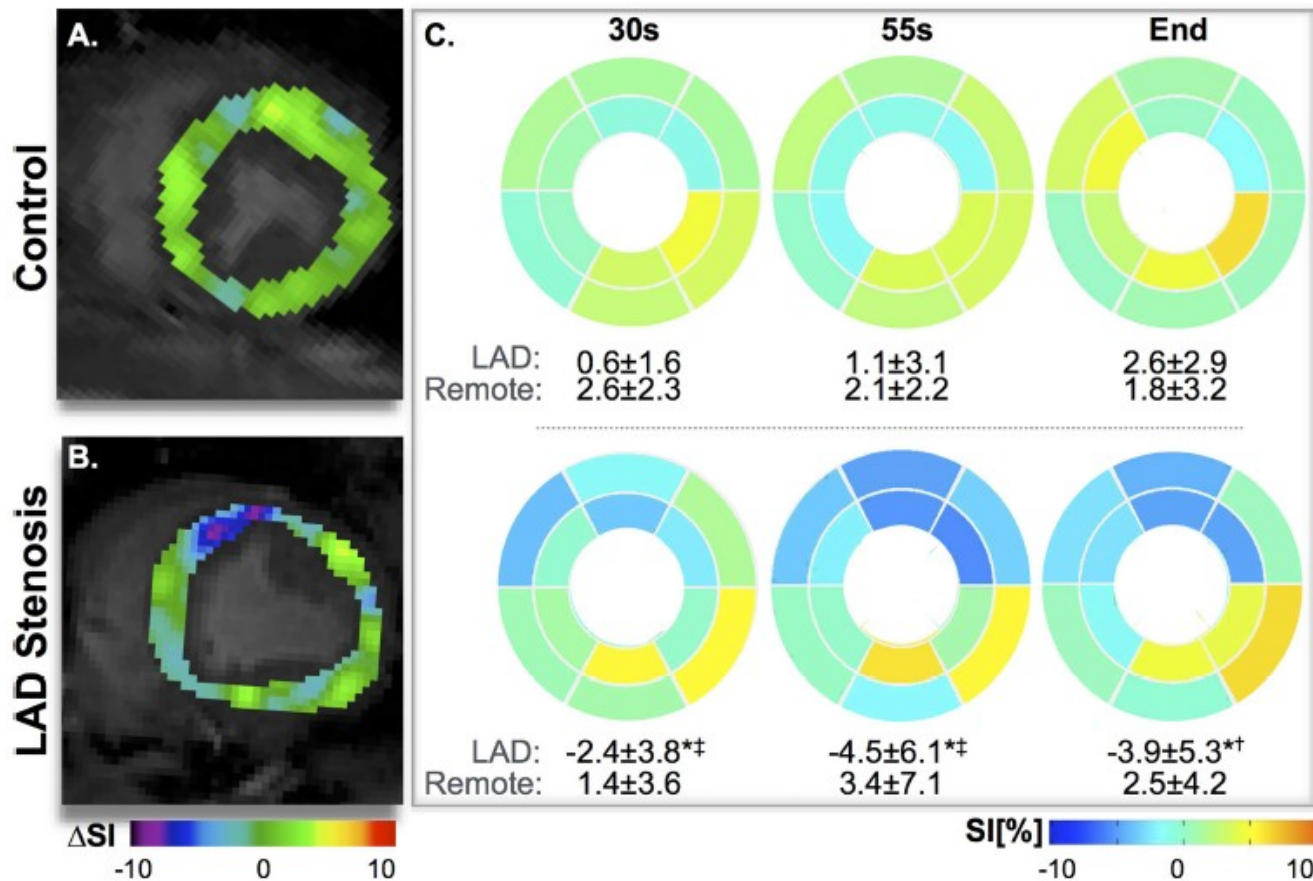

**Fig 2. Breathing maneuver protocol.** For the combined hyperventilation breath-hold (HVBH) maneuver, a single rest measurement was obtained in a short breath-hold (A). The animal was then manually hyperventilated for 60s (B) followed immediately by a long breath-hold (C) that was imaged throughout, with a repeating OS sequence. Hyperventilation analysis was always compared between rest and the start of the breath-hold (red arrow), while the breath-hold could be analyzed at multiple time points with comparison to data obtained at the beginning of the breath-hold (purple arrow). The long breath-hold (LBH) followed step C, starting after a normal ventilation pattern.

doi:10.1371/journal.pone.0164524.g002

**Fig 4. Segmental changes of myocardial oxygenation during the HVBH.** Subtraction images (smoothed using a 6mm Gaussian filter) demonstrate that at the 30s, SI increased homogeneously in the control animal (A), while there was a decrease in the territory of the stenosed LAD (B). The mean response for each segment from all animals similarly shows that in control animals (top row,  $n = 8$ ),  $\Delta SI[\%]$  is consistently larger for all segments, whereas for the stenosis animals (bottom row,  $n = 10$ ) in the LAD regions a significant decrease is already observed at 30s, and this continues throughout the breath-hold. ( $*p < 0.05$  between LAD and remote territory within the group,  $†p < 0.05$ ,  $< 0.05 \ddagger p < 0.01$  for the difference in LAD response between groups).

doi:10.1371/journal.pone.0164524.g004

**Fig 5. Myocardial oxygenation response curve during the HVBH.** Signal intensity increases globally during the HVBH in control animals (A), yet the animals with a stenosis (B) show a significant decrease in the LAD territory (blue), while the remote region (green) remains above baseline with a similar characteristic of the control animals.
